

BASIC NETWORKING COMMANDS

AIM:

To familiarise the basics of network configuration files and networking commands in Linux.

THEORY:

- **IFCONFIG** - configure a network interface
Ifconfig is used to configure the kernel-resident network interfaces. It is used at boot time to set up interfaces as necessary. After that, it is usually only needed when debugging or when system tuning is needed.
If no arguments are given, ifconfig displays the status of the currently active interfaces. If a single interface argument is given, it displays the status of the given interface only; if a single -a argument is given, it displays the status of all interfaces, even those that are down. Otherwise, it configures an interface.
- **NETSTAT** - Print network connections, routing tables, interface statistics, masquerade connections, and multicast memberships.
Netstat prints information about the Linux networking subsystem. The type of information printed is controlled by the first argument, as follows:

(none)
By default, netstat displays a list of open sockets. If you don't specify any address families, then the active sockets of all configured address families will be printed.

--route, -r
Display the kernel routing tables.

--groups, -g
Display multicast group membership information for IPv4 and IPv6.

--interfaces, -i
Display a table of all network interfaces.

--masquerade, -M
Display a list of masqueraded connections.

--statistics, -s
Display summary statistics for each protocol.
- **PING** - send ICMP ECHO_REQUEST to network hosts
ping uses the ICMP protocol's mandatory ECHO_REQUEST datagram to elicit an ICMP ECHO_RESPONSE from a host or gateway. ECHO_REQUEST datagrams ("pings") have an IP and ICMP header, followed by a struct timeval and then an arbitrary number of "pad" bytes used to fill out the packet.
ping works with both IPv4 and IPv6. Using only one of them explicitly can be enforced by specifying -4 or -6. ping can also send IPv6 Node Information Queries (RFC4620). Intermediate hops may not be allowed, because IPv6 source routing was deprecated (RFC5095).

```
$ arp -n
Address                HWtype  HWaddress           Flags Mask    Iface

```

- **ARP** - manipulate the system ARP cache
Arp manipulates or displays the kernel's IPv4 network neighbour cache. It can add entries to the table, delete one or display the current content.

ARP stands for Address Resolution Protocol, which is used to find the media access control address of a network neighbour for a given IPv4 Address.

- **TELNET** - user interface to the TELNET protocol
The telnet command is used for interactive communication with another host using the TELNET protocol. It begins in command mode, where it prints a telnet prompt ("telnet> "). If telnet is invoked with a host argument, it performs an open command implicitly.
- **FTP** - Internet file transfer program
Ftp is the user interface to the Internet standard File Transfer Protocol. The program allows a user to transfer files to and from a remote network site.

The client host and an optional port number with which ftp is to communicate may be specified on the command line. If this is done, ftp will immediately attempt to establish a connection to an FTP server on that host; otherwise, ftp will enter its command interpreter and await instructions from the user. When ftp is awaiting commands from the user the prompt 'ftp>' is provided to the user.

- **FINGER** - user information lookup program
The finger displays information about the system users.
Options are:

-s Finger displays the user's login name, real name, terminal name and write status (as a ``*" after the terminal name if write permission is denied), idle time, login time, office location and office phone number.

-l Produces a multi-line format displaying all of the information described for the -s option as well as the user's home directory, home phone number, login shell, mail status, and the contents of the files ".plan", ".project", ".pgpkey" and ".forward" from the user's home directory.

-p Prevents the -l option of finger from displaying the contents of the ".plan", ".project" and ".pgpkey" files.

-m Prevent matching of user names. User is usually a login name; however, matching will also be done on the users' real names, unless the -m option is supplied. All name matching performed by finger is case insensitive.

If no options are specified, finger defaults to the -l style output if operands are provided, otherwise to the -s style. Note that some fields may be missing, in either format, if information is not available for them.

If no arguments are specified, finger will print an entry for each user currently logged into the system.

Finger may be used to look up users on a remote machine. The format is to specify a user as "user@host", or "@host", where the default output format for the former is the -l style, and the default output format for the latter is the -s style. The -l option is the only option that may be passed to a remote machine.

If standard output is a socket, finger will emit a carriage return (^M) before every linefeed (^J). This is for processing remote finger requests when invoked by fingerd(8).

- **TRACEROUTE** - print the route packets trace to network host
tracert tracks the route packets taken from an IP network on their way to a given host. It utilizes the IP protocol's time to live (TTL) field and attempts to elicit an ICMP TIME_EXCEEDED response from each gateway along the path to the host.

tracert6 is equivalent to tracert -6

tcptracert is equivalent to tracert -T

lft, the Layer Four Traceroute, performs a TCP traceroute, like tracert -T, but attempts to provide compatibility with the original such implementation, also called "lft".

The only required parameter is the name or IP address of the destination host. The optional packet_length is the total size of the probing packet (default 60 bytes for IPv4 and 80 for IPv6). The specified size can be ignored in some situations or increased up to a minimal value.

This program attempts to trace the route an IP packet would follow to some internet host by launching probe packets with a small ttl (time to live) then listening for an ICMP "time exceeded" reply from a gateway. We start our probes with a ttl of one and increase by one until we get an ICMP "port unreachable" (or TCP reset), which means we got to the "host", or hit a max (which defaults to 30 hops). Three probes (by default) are sent at each ttl setting and a line is printed showing the ttl, address of the gateway and round trip time of each probe. The address can be followed by additional information when requested. If the probe answers come from different gateways, the address of each responding system will be printed. If there is no response within a certain timeout, an "*" (asterisk) is printed for that probe.

After the trip time, some additional annotation can be printed: !H, !N, or !P (host, network or protocol unreachable), !S (source route failed), !F (fragmentation needed), !X (communication administratively prohibited), !V (host precedence violation), !C (precedence cutoff in effect), or !<num> (ICMP unreachable code <num>). If almost all the probes result in some kind of unreachable, tracert will give up and exit.

We don't want the destination host to process the UDP probe packets, so the destination port is set to an unlikely value (you can change it with the -p flag). There is no such a problem for ICMP or TCP tracerouting (for TCP we use half-open technique, which prevents our probes to be seen by applications on the destination host).

In the modern network environment the traditional traceroute methods can not be always applicable, because of widespread use of firewalls. Such firewalls filter the "unlikely" UDP ports, or even ICMP echoes.

- **WHOIS** - client for the whois directory service
whois searches for an object in a RFC 3912 database.

This version of the whois client tries to guess the right server to ask for the specified object. If no guess can be made it will connect to whois.networksolutions.com for NIC handles or whois.arin.net for IPv4 addresses and network names.

RESULT:

Basics of network configuration files and networking commands in Linux were understood.

SOCKET PROGRAMMING

AIM:

To familiarize and understand the use and functioning of system calls used for network programming in Linux.

THEORY:

SOCKET OPERATIONS

▪ **SOCKET(2)**

NAME

socket - create an endpoint for communication

SYNOPSIS

```
#include <sys/types.h>
#include <sys/socket.h>
int socket(int domain, int type, int protocol);
```

DESCRIPTION

socket() creates an endpoint for communication and returns a file descriptor that refers to that endpoint. The file descriptor returned by a successful call will be the lowest-numbered file descriptor not currently open for the process.

The domain argument specifies a communication domain; this selects the protocol family which will be used for communication. These families are defined in <sys/socket.h>.

RETURN VALUE

On success, a file descriptor for the new socket is returned. On error, -1 is returned, and errno is set appropriately.

▪ **SOCKETPAIR(2)**

NAME

socketpair - create a pair of connected sockets

SYNOPSIS

```
#include <sys/types.h>
#include <sys/socket.h>
int socketpair(int domain, int type, int protocol, int sv[2]);
```

DESCRIPTION

The `socketpair()` call creates an unnamed pair of connected sockets in the specified domain, of the specified type, and using the optionally specified protocol. For further details of these arguments, see `socket(2)`.

The file descriptors used in referencing the new sockets are returned in `sv[0]` and `sv[1]`. The two sockets are indistinguishable.

RETURN VALUE

On success, zero is returned. On error, -1 is returned, `errno` is set appropriately, and `sv` is left unchanged.

On Linux (and other systems), `socketpair()` does not modify `sv` on failure. A requirement standardizing this behavior was added in POSIX.1-2016.

▪ GETSOCKOPT(2) and SETSOCKOPT(2)

NAME

`getsockopt`, `setsockopt` - get and set options on sockets

SYNOPSIS

```
#include <sys/types.h>           /* See NOTES */
#include <sys/socket.h>

int getsockopt(int sockfd, int level, int optname,
               void *optval, socklen_t *optlen);

int setsockopt(int sockfd, int level, int optname,
               const void *optval, socklen_t optlen);
```

DESCRIPTION

`getsockopt()` and `setsockopt()` manipulate options for the socket referred to by the file descriptor `sockfd`. Options may exist at multiple protocol levels; they are always present at the uppermost socket level.

When manipulating socket options, the level at which the option resides and the name of the option must be specified.

The arguments `optval` and `optlen` are used to access option values for `setsockopt()`. For `getsockopt()` they identify a buffer in which the value for the requested option(s) are to be returned. For `setsockopt()`, `optlen` is a value-result argument, initially containing the size of the buffer pointed to by `optval`, and modified on return to indicate the actual size of the value returned. If no option value is to be supplied or returned, `optval` may be `NULL`.

RETURN VALUE

On success, zero is returned for the standard options. On error, -1 is returned, and `errno` is set appropriately.

Netfilter allows the programmer to define custom socket options with associated handlers; for such options, the return value on success is the value returned by the handler.

- **GETSOCKNAME(2)**

NAME

getsockname - get socket name

SYNOPSIS

```
#include <sys/socket.h>
```

```
int getsockname(int sockfd, struct sockaddr *addr, socklen_t *addrlen);
```

DESCRIPTION

getsockname() returns the current address to which the socket sockfd is bound, in the buffer pointed to by addr. The addrlen argument should be initialized to indicate the amount of space (in bytes) pointed to by addr. On return it contains the actual size of the socket address.

The returned address is truncated if the buffer provided is too small; in this case, addrlen will return a value greater than was supplied to the call.

RETURN VALUE

On success, zero is returned. On error, -1 is returned, and errno is set appropriately.

- **GETPEERNAME(2)**

NAME

getpeername - get name of connected peer socket

SYNOPSIS

```
#include <sys/socket.h>
```

```
int getpeername(int sockfd, struct sockaddr *addr, socklen_t *addrlen);
```

DESCRIPTION

getpeername() returns the address of the peer connected to the socket sockfd, in the buffer pointed to by addr. The addrlen argument should be initialized to indicate the amount of space pointed to by addr. On return it contains the actual size of the name returned (in bytes). The name is truncated if the buffer provided is too small.

The returned address is truncated if the buffer provided is too small; in this case, addrlen will return a value greater than was supplied to the call.

RETURN VALUE

On success, zero is returned. On error, -1 is returned, and errno is set appropriately.

- **BIND(2)**

NAME

bind - bind a name to a socket

SYNOPSIS

```
#include <sys/types.h>          /* See NOTES */
#include <sys/socket.h>
int bind(int sockfd, const struct sockaddr *addr,
        socklen_t addrlen);
```

DESCRIPTION

When a socket is created with `socket(2)`, it exists in a name space (address family) but has no address assigned to it. `bind()` assigns the address specified by `addr` to the socket referred to by the file descriptor `sockfd`. `addrlen` specifies the size, in bytes, of the address structure pointed to by `addr`. Traditionally, this operation is called “assigning a name to a socket”.

It is normally necessary to assign a local address using `bind()` before a `SOCK_STREAM` socket may receive connections.

RETURN VALUE

On success, zero is returned. On error, -1 is returned, and `errno` is set appropriately.

▪ ACCEPT(2)

NAME

`accept`, `accept4` - accept a connection on a socket

SYNOPSIS

```
#include <sys/types.h>          /* See NOTES */
#include <sys/socket.h>
int accept(int sockfd, struct sockaddr *addr, socklen_t *addrlen);

#define _GNU_SOURCE             /* See feature_test_macros(7) */
#include <sys/socket.h>
int accept4(int sockfd, struct sockaddr *addr,
            socklen_t *addrlen, int flags);
```

DESCRIPTION

The `accept()` system call is used with connection-based socket types (`SOCK_STREAM`, `SOCK_SEQPACKET`).

It extracts the first connection request on the queue of pending connections for the listening socket, `sockfd`, creates a new connected socket, and returns a new file descriptor referring to that socket. The newly created socket is not in the listening state. The original socket `sockfd` is unaffected by this call.

The argument `sockfd` is a socket that has been created with `socket(2)`, bound to a local address with `bind(2)`, and is listening for connections after a `listen(2)`.

The argument `addr` is a pointer to a `sockaddr` structure. This structure is filled in with the address of the peer socket, as known to the communications layer.

The `addrlen` argument is a value-result argument: the caller must initialize it to contain the size (in bytes) of the structure pointed to by `addr`; on return it will contain the actual size of the peer address.

The returned address is truncated if the buffer provided is too small; in this case, `addrlen` will return a value greater than was supplied to the call.

If no pending connections are present on the queue, and the socket is not marked as nonblocking, `accept()` blocks the caller until a connection is present. If the socket is marked nonblocking and no pending connections are present on the queue, `accept()` fails with the error `EAGAIN` or `EWOULDBLOCK`.

In order to be notified of incoming connections on a socket, you can use `select(2)`, `poll(2)`, or `epoll(7)`. A readable event will be delivered when a new connection is attempted and you may then call `accept()` to get a socket for that connection.

If `flags` is 0, then `accept4()` is the same as `accept()`.

RETURN VALUE

On success, these system calls return a nonnegative integer that is a file descriptor for the accepted socket. On error, -1 is returned, `errno` is set appropriately, and `addrlen` is left unchanged.

▪ CONNECT(2)

NAME

`connect` - initiate a connection on a socket

SYNOPSIS

```
#include <sys/types.h>          /* See NOTES */
#include <sys/socket.h>
int connect(int sockfd, const struct sockaddr *addr,
            socklen_t addrlen);
```

DESCRIPTION

The `connect()` system call connects the socket referred to by the file descriptor `sockfd` to the address specified by `addr`. The `addrlen` argument specifies the size of `addr`. The format of the address in `addr` is determined by the address space of the socket `sockfd`.

If the socket `sockfd` is of type `SOCK_DGRAM`, then `addr` is the address to which datagrams are sent by default, and the only address from which datagrams are received. If the socket is of type `SOCK_STREAM` or `SOCK_SEQPACKET`, this call attempts to make a connection to the socket that is bound to the address specified by `addr`.

Generally, connection-based protocol sockets may successfully `connect()` only once; connectionless protocol sockets may use `connect()` multiple times to change their association.

RETURN VALUE

If the connection or binding succeeds, zero is returned. On error, -1 is returned, and `errno` is set appropriately.

▪ SHUTDOWN(2)

NAME

shutdown - shut down part of a full-duplex connection

SYNOPSIS

```
#include <sys/socket.h>
int shutdown(int sockfd, int how);
```

DESCRIPTION

The shutdown() call causes all or part of a full-duplex connection on the socket associated with sockfd to be shutdown. If how is SHUT_RD, further receptions will be disallowed. If how is SHUT_WR, further transmissions will be disallowed. If how is SHUT_RDWR, further receptions and transmissions will be disallowed.

RETURN VALUE

On success, zero is returned. On error, -1 is returned, and errno is set appropriately.

SEND OR RECEIVE OPERATIONS

▪ SEND(2)

NAME

send, sendto, sendmsg - send a message on a socket

SYNOPSIS

```
#include <sys/types.h>
#include <sys/socket.h>

ssize_t send(int sockfd, const void *buf, size_t len, int flags);

ssize_t sendto(int sockfd, const void *buf, size_t len, int flags,
               const struct sockaddr *dest_addr, socklen_t addrlen);

ssize_t sendmsg(int sockfd, const struct msghdr *msg, int flags);
```

DESCRIPTION

The system calls send(), sendto(), and sendmsg() are used to transmit a message to another socket.

The send() call may be used only when the socket is in a connected state (so that the intended recipient is known). The only difference between send() and write(2) is the presence of flags. With a zero flags argument, send() is equivalent to write(2). Also, the following call

```
send(sockfd, buf, len, flags);
```

is equivalent to

```
sendto(sockfd, buf, len, flags, NULL, 0);
```

The argument sockfd is the file descriptor of the sending socket.

If `sendto()` is used on a connection-mode (`SOCK_STREAM`, `SOCK_SEQPACKET`) socket, the arguments `dest_addr` and `addrlen` are ignored (and the error `EISCONN` may be returned when they are not `NULL` and 0), and the error `ENOTCONN` is returned when the socket was not actually connected. Otherwise, the address of the target is given by `dest_addr` with `addrlen` specifying its size. For `sendmsg()`, the address of the target is given by `msg.msg_name`, with `msg.msg_namelen` specifying its size.

For `send()` and `sendto()`, the message is found in `buf` and has length `len`. For `sendmsg()`, the message is pointed to by the elements of the array `msg.msg_iov`. The `sendmsg()` call also allows sending ancillary data (also known as control information).

If the message is too long to pass atomically through the underlying protocol, the error `EMSGSIZE` is returned, and the message is not transmitted.

No indication of failure to deliver is implicit in a `send()`. Locally detected errors are indicated by a return value of -1.

When the message does not fit into the send buffer of the socket, `send()` normally blocks, unless the socket has been placed in nonblocking I/O mode. In nonblocking mode it would fail with the error `EAGAIN` or `EWOULDBLOCK` in this case. The `select(2)` call may be used to determine when it is possible to send more data.

RETURN VALUE

On success, these calls return the number of bytes sent. On error, -1 is returned, and `errno` is set appropriately.

▪ SENDMSG(2)

NAME

`sendmsg` - send multiple messages on a socket

SYNOPSIS

```
#define _GNU_SOURCE          /* See feature_test_macros(7) */
#include <sys/socket.h>

int sendmsg(int sockfd, struct mmsghdr *msgvec, unsigned int vlen,
            int flags);
```

DESCRIPTION

The `sendmsg()` system call is an extension of `sendmsg(2)` that allows the caller to transmit multiple messages on a socket using a single system call. (This has performance benefits for some applications.)

The `sockfd` argument is the file descriptor of the socket on which data is to be transmitted.

The `msgvec` argument is a pointer to an array of `mmsghdr` structures. The size of this array is specified in `vlen`.

The `mmsghdr` structure is defined in `<sys/socket.h>` as:

```
struct mmsghdr {
    struct msghdr msg_hdr; /* Message header */
    unsigned int  msg_len; /* Number of bytes transmitted */
};
```

The `msg_hdr` field is a `msghdr` structure, as described in `sendmsg(2)`. The `msg_len` field is used to return the number of bytes sent from the message in `msg_hdr` (i.e., the same as the return value from a single `sendmsg(2)` call).

The `flags` argument contains flags ORed together. The flags are the same as for `sendmsg(2)`.

A blocking `sendmmsg()` call blocks until `vlen` messages have been sent. A nonblocking call sends as many messages as possible (up to the limit specified by `vlen`) and returns immediately.

On return from `sendmmsg()`, the `msg_len` fields of successive elements of `msgvec` are updated to contain the number of bytes transmitted from the corresponding `msg_hdr`. The return value of the call indicates the number of elements of `msgvec` that have been updated.

RETURN VALUE

On success, `sendmmsg()` returns the number of messages sent from `msgvec`; if this is less than `vlen`, the caller can retry with a further `sendmmsg()` call to send the remaining messages.

▪ RECV(2)

NAME

`recv`, `recvfrom`, `recvmsg` - receive a message from a socket

SYNOPSIS

```
#include <sys/types.h>
#include <sys/socket.h>
ssize_t recv(int sockfd, void *buf, size_t len, int flags);
ssize_t recvfrom(int sockfd, void *buf, size_t len, int flags,
                 struct sockaddr *src_addr, socklen_t *addrlen);
ssize_t recvmsg(int sockfd, struct msghdr *msg, int flags);
```

DESCRIPTION

The `recv()`, `recvfrom()`, and `recvmsg()` calls are used to receive messages from a socket. They may be used to receive data on both connectionless and connection-oriented sockets.

The only difference between `recv()` and `read(2)` is the presence of flags. With a zero flags argument, `recv()` is generally equivalent to `read(2)` (but see NOTES). Also, the following call

```
recv(sockfd, buf, len, flags);
```

is equivalent to

```
recvfrom(sockfd, buf, len, flags, NULL, NULL);
```

All three calls return the length of the message on successful completion. If a message is too long to fit in the supplied buffer, excess bytes may be discarded depending on the type of socket the message is received from.

If no messages are available at the socket, the receive calls wait for a message to arrive, unless the socket is nonblocking, in which case the value -1 is returned and the external variable `errno` is set to `EAGAIN` or `EWOULDBLOCK`. The receive calls normally return any data available, up to the requested amount, rather than waiting for receipt of the full amount requested.

An application can use `select(2)`, `poll(2)`, or `epoll(7)` to determine when more data arrives on a socket.

recvfrom()

recvfrom() places the received message into the buffer buf. The caller must specify the size of the buffer in len.

If src_addr is not NULL, and the underlying protocol provides the source address of the message, that source address is placed in the buffer pointed to by src_addr. In this case, addrlen is a value-result argument. Before the call, it should be initialized to the size of the buffer associated with src_addr. Upon return, addrlen is updated to contain the actual size of the source address.

The returned address is truncated if the buffer provided is too small; in this case, addrlen will return a value greater than was supplied to the call.

If the caller is not interested in the source address, src_addr and addrlen should be specified as NULL.

recv()

The recv() call is normally used only on a connected socket (see connect(2)). It is equivalent to the call:

```
recvfrom(fd, buf, len, flags, NULL, 0);
```

recvmsg()

The recvmsg() call uses a msghdr structure to minimize the number of directly supplied arguments.

RETURN VALUE

These calls return the number of bytes received, or -1 if an error occurred. In the event of an error, errno is set to indicate the error.

When a stream socket peer has performed an orderly shutdown, the return value will be 0 (the traditional "end-of-file" return).

Datagram sockets in various domains (e.g., the UNIX and Internet domains) permit zero-length datagrams. When such a datagram is received, the return value is 0.

The value 0 may also be returned if the requested number of bytes to receive from a stream socket was 0.

▪ RECVMSG(2)

NAME

recvmsg - receive multiple messages on a socket

SYNOPSIS

```
#define _GNU_SOURCE          /* See feature_test_macros(7) */
#include <sys/socket.h>
int recvmsg(int sockfd, struct msghdr *msgvec, unsigned int vlen,
            int flags, struct timespec *timeout);
```

DESCRIPTION

The recvmsg() system call is an extension of recvmsg(2) that allows the caller to receive multiple messages from a socket using a single system call. (This has performance benefits for some applications.) A further extension over recvmsg(2) is support for a timeout on the receive operation.

The sockfd argument is the file descriptor of the socket to receive data from.

The msgvec argument is a pointer to an array of mmsghdr structures. The size of this array is specified in vlen.

The mmsghdr structure is defined in <sys/socket.h> as:

```
struct mmsghdr {
    struct msghdr msg_hdr; /* Message header */
    unsigned int  msg_len; /* Number of received bytes for header
*/
};
```

The msg_hdr field is a msghdr structure, as described in recvmsg(2). The msg_len field is the number of bytes returned for the message in the entry. This field has the same value as the return value of a single recvmsg(2) on the header.

The timeout argument points to a struct timespec defining a timeout (seconds plus nanoseconds) for the receive operation. (This interval will be rounded up to the system clock granularity, and kernel scheduling delays mean that the blocking interval may overrun by a small amount.) If timeout is NULL, then the operation blocks indefinitely.

A blocking recvmsg() call blocks until vlen messages have been received or until the timeout expires. A nonblocking call reads as many messages as are available (up to the limit specified by vlen) and returns immediately.

On return from recvmsg(), successive elements of msgvec are updated to contain information about each received message: msg_len contains the size of the received message; the subfields of msg_hdr are updated as described in recvmsg(2). The return value of the call indicates the number of elements of msgvec that have been updated.

RETURN VALUE

On success, recvmsg() returns the number of messages received in msgvec; on error, -1 is returned, and errno is set to indicate the error.

RESULT:

The use of system calls used for networking programming in Linux was familiarised and understood.

PROGRAM:

// Server (TCP)

```
#include <sys/socket.h>
#include <netinet/in.h>
#include <stdio.h>
#include <string.h>
#include <stdlib.h>

int main()
{
    char buf[100];
    int k;
    socklen_t len;
    int sock_desc, temp_sock_desc;
    struct sockaddr_in server, client;

    sock_desc = socket(AF_INET, SOCK_STREAM, 0);
    if (sock_desc == -1)
        printf("Error in socketcreation");
    server.sin_family = AF_INET;
    server.sin_addr.s_addr = INADDR_ANY;
    server.sin_port = 3003;
    client.sin_family = AF_INET;
    client.sin_addr.s_addr = INADDR_ANY;
    client.sin_port = 3003;

    k = bind(sock_desc, (struct sockaddr *)&server, sizeof(server));
    if (k == -1)
        printf("Error in binding");

    k = listen(sock_desc, 5);
    if (k == -1)
        printf("Error in listening");

    len = sizeof(client);
    temp_sock_desc = accept(sock_desc, (struct sockaddr *)&client, &len);
    if (temp_sock_desc == -1)
        printf("Error in temporary socket creation");

    k = recv(temp_sock_desc, buf, 100, 0);
    if (k == -1)
        printf("Error in receiving");

    printf("Message got from client: %s", buf);

    close(temp_sock_desc);
    return 0;
}
```

// Client (TCP)

```
#include <sys/socket.h>
#include <netinet/in.h>
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
```

TRANSMISSION CONTROL PROTOCOL

AIM:

To implement client-server communication using socket programming and TCP as transport layer protocol.

THEORY:

A TCP (transmission control protocol) is a connection-oriented communication. TCP is designed to send the data packets over the network. It ensures that data is delivered to the correct destination. TCP creates a connection between the source and destination node before transmitting the data and keeps the connection alive until the communication is active.

Server-client model is communication model for sharing the resource and provides the service to different machines. Server is the main system which provides the resources and different kind of services when client requests to use it.

ALGORITHM:

Server

1. Create a socket with type as `SOCK_STREAM` to create a tcp socket using `socket()` system call.
2. Bind the socket to a specific port using `bind()` system call.
3. Listen for new connections using the `listen()` system call.
4. Accept connection from client process into a temporary socket.
5. Read the message from the client using the `recv()` system call into a buffer.
6. Display the message and close the socket.

Client

1. Create a socket with type as `SOCK_STREAM` to create a tcp socket using `socket()` system call.
2. Connect to the server using `connect()` system call.
3. Read the message to be sent from the user.
4. Send the message to the server using `send()` system call.
5. Close the socket.

```

int main()
{
    char buf[100];
    int k;
    int sock_desc;
    struct sockaddr_in client;

    sock_desc = socket(AF_INET, SOCK_STREAM, 0);
    if (sock_desc == -1)
        printf("Error in socket creation!");

    client.sin_family = AF_INET;
    client.sin_addr.s_addr = INADDR_ANY;
    client.sin_port = 3003;

    k = connect(sock_desc, (struct sockaddr *)&client, sizeof(client));
    if (k == -1)
        printf("Error in connecting to server!");

    printf("\nEnter data to be send: ");
    fgets(buf, 100, stdin);

    k = send(sock_desc, buf, 100, 0);
    if (k == -1)
        printf("Error in sending!");

    close(sock_desc);
    return 0;
}

```

OUTPUT:

// Terminal 1

```
$ gcc -o server server.c
```

```
$ ./server
```

```
-
```

// Terminal 2

```
$ gcc -o client client.c
```

```
$ ./client
```

```
Enter data to be send: hi programmers!
```

// Terminal 1

```
$ gcc -o server server.c
```

```
$ ./server
```

```
Message got from client: hi programmers!
```

RESULT:

The programs for client-server communication using socket programming for TCP was executed and output was verified successfully.

PROGRAM:

// Server (UDP)

```
#include <sys/socket.h>
#include <netinet/in.h>
#include <stdio.h>
#include <string.h>
#include <stdlib.h>

int main(int argc, char *argv[])
{
    struct sockaddr_in server, client;

    if (argc != 2)
        printf("Input format not correct!\n");

    int sockfd = socket(AF_INET, SOCK_DGRAM, 0);
    if (sockfd == -1)
        printf("Error in socket creation!\n");

    server.sin_family = AF_INET;
    server.sin_addr.s_addr = INADDR_ANY;
    server.sin_port = htons(atoi(argv[1]));

    if (bind(sockfd, (struct sockaddr *)&server, sizeof(server)) < 0)
        printf("Error in bind()!\n");

    char buffer[100];
    socklen_t server_len = sizeof(server);
    printf("Server waiting...\n");

    if (recvfrom(sockfd, buffer, 100, 0, (struct sockaddr *)&server, &server_len)
    < 0)
        printf("Error in receiving!\n");

    printf("Got a datagram: %s", buffer);

    return 0;
}
```

// Client (UDP)

```
#include <sys/socket.h>
#include <netinet/in.h>
#include <stdio.h>
#include <string.h>
#include <stdlib.h>

int main(int argc, char *argv[])
{
    struct sockaddr_in server, client;

    if (argc != 3)
        printf("Input format not correct!\n");

    int sockfd = socket(AF_INET, SOCK_DGRAM, 0);
    if (sockfd == -1)
        printf("Error in socket creation!\n");
```

USER DATAGRAM PROTOCOL

AIM:

To implement client-server communication using socket programming and UDP as transport layer protocol.

THEORY:

UDP is a connection-less protocol that, unlike TCP, does not require any handshaking prior to sending or receiving data, which simplifies its implementation. In UDP, the client does not form a connection with the server like in TCP and instead just sends a datagram. Similarly, the server need not accept a connection and just waits for datagrams to arrive.

Server-client model is communication model for sharing the resource and provides the service to different machines. Server is the main system which provides the resources and different kind of services when client requests to use it.

ALGORITHM:

Server

1. Create a socket with type as `SOCK_DGRAM` to create a udp socket using `socket()` system call.
2. Bind the socket to a specific port using `bind()` system call.
3. Using the `recvfrom()` system call message sent from the client process into a buffer.
4. Display the message and close the socket.

Client

1. Create a socket with type as `SOCK_DGRAM` to create a udp socket using `socket()` system call.
2. Read the message to be sent from the user.
3. Send the message to the server using `sendto()` system call.
4. Close the socket.

```

server.sin_family = AF_INET;
server.sin_addr.s_addr = INADDR_ANY;
server.sin_port = htons(atoi(argv[2]));

char buffer[100];
printf("Enter a message to sent to server: ");
fgets(buffer, 100, stdin);

if (sendto(sockfd, buffer, sizeof(buffer), 0, (struct sockaddr *)&server,
sizeof(server)) < 0)
    printf("Error in sending!\n");

return 0;
}

```

OUTPUT:

// Terminal 1

```

$ gcc -o server server.c
$ ./server 2000
Server waiting...

```

// Terminal 2

```

$ gcc -o client client.c
$ ./client localhost 2000
Enter a message to sent to server: Morning!

```

// Terminal 1

```

$ gcc -o server server.c
$ ./server 2000
Server waiting...
Got a datagram: Morning!

```

RESULT:

The programs for client-server communication using socket programming for UDP was executed and output was verified successfully.

PROGRAM:

// Stop and Wait Protocol

```
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>

int main()
{
    int i, j = 0, noframes, x, x1 = 10, x2;

    printf("Enter the number of frames: ");
    scanf("%d", &noframes);
    printf("\nnumber of frames is %d", noframes);

    while (noframes > 0)
    {
        printf("\nsending frame %d", i);
        srand(x1++); // The srand() function sets the starting point for producing
a series of pseudo-random integers
        x = rand() % 10;
        if (x % 2 == 0)
        {
            for (x2 = 1; x2 < 2; x2++)
            {
                printf("\nwaiting for %d seconds\n", x2);
                sleep(x2);
                printf("Missing Acknowledgement %d", i);
            }
            printf("\nsending frame %d", i);
            srand(x1++);
            x = rand() % 10;
        }
        printf("\nack received for frame %d", j);
        noframes -= 1;
        i++;
        j++;
    }
    printf("\nend of stop and wait protocol\n");

    return 0;
}
```

STOP AND WAIT PROTOCOL

AIM:

To write a program to simulate the stop and wait protocol.

THEORY:

Sliding window protocols are data link layer protocols for reliable and sequential delivery of data frames. In this protocol, multiple frames can be sent by a sender at a time before receiving an acknowledgment from the receiver. The term sliding window refers to the imaginary boxes to hold frames.

It is the simplest flow control method. In this, the sender will transmit one frame at a time to the receiver. The sender will stop and wait for the acknowledgment from the receiver. When the sender gets the acknowledgment (ACK), it will send the next data packet to the receiver and wait for the disclosure again, and this process will continue as long as the sender has the data to send. The sender and receiver window size is 1.

ALGORITHM:

1. *Start the program, declare the variable.*
2. *Determine the packet size in bytes.*
3. *In the flow control, the sender sends a single frame to receiver & waits for an acknowledgment.*
4. *Wait for an event to happen and return its type is event.*
5. *Fetch a packet from the network layer for transmission on the channel.*
6. *The next frame is sent by sender only when acknowledgment of previous frame is received.*
7. *The process of sending a frame & waiting for an acknowledgment continues as long as the sender has data to send.*
8. *To end up the transmission sender transmits end of transmission (EOT) frame.*

OUTPUT:

```
$ gcc main.c
$ ./a.out
Enter the number of frames: 6

number of frames is 6
sending frame 0
ack received for frame 0
sending frame 1
ack received for frame 1
sending frame 2
waiting for 1 seconds
Missing Acknowledgement 2
sending frame 2
ack received for frame 2
sending frame 3
ack received for frame 3
sending frame 4
ack received for frame 4
sending frame 5
waiting for 1 seconds
Missing Acknowledgement 5
sending frame 5
ack received for frame 5

end of stop and wait protocol
```

RESULT:

The program for Stop and Wait protocol was executed and output was verified successfully.

PROGRAM:

```
// Server (Go Back N)
#include <stdio.h>
#include <stdlib.h>
#include <sys/socket.h>
#include <sys/types.h>
#include <sys/time.h>

    buff2[strlen(msg)] = i + '\0';
    printf("Message sent to client: %s \n", buff2);
    write(c_sock, buff2, sizeof(buff2));
```

GO BACK N

AIM:

To write a program to simulate the Go Back N.

THEORY:

Sliding window protocols are data link layer protocols for reliable and sequential delivery of data frames. In this protocol, multiple frames can be sent by a sender at a time before receiving an acknowledgment from the receiver. The term sliding window refers to the imaginary boxes to hold frames.

Go-Back-N ARQ protocol is also known as Go-Back-N Automatic Repeat Request. In this, if any frame is corrupted or lost, all subsequent frames have to be sent again. The size of the sender window is N in this protocol. The receiver window size is always 1. If the receiver receives a corrupted frame, it cancels it. The receiver does not accept a corrupted frame. When the timer expires, the sender sends the correct frame again.

PSEUDOCODE:

Go-Back-N Sender Algorithm

```
begin
    frame s;           //s denotes frame to be sent
    frame t;           //t is temporary frame
    S_window = power(2,m) - 1; //Assign maximum window size
    SeqFirst = 0;      // Sequence number of first frame in window
    SeqN = 0;          // Sequence number of Nth frame window
    while (true)       //check repeatedly
    do
        Wait_For_Event(); //wait for availability of packet
        if ( Event(Request_For_Transfer)) then
            //check if window is full
            if (SeqN-SeqFirst >= S_window) then
                doNothing();
            end if;
            Get_Data_From_Network_Layer();
            s = Make_Frame();
            s.seq = SeqN;
            Store_Copy_Frame(s);
            Send_Frame(s);
            Start_Timer(s);
            SeqN = SeqN + 1;
        end if;
```

```

        i = i + 1;
        usleep(1000);
qqq:bzero(buff2, sizeof(buff2));

SELECTIVE REPEAT

AIM:

To write a program to simulate the Selective Repeat protocol.

THEORY:

Sliding window protocols are data link layer protocols for reliable and sequential delivery of data frames. In this protocol, multiple frames can be sent by a sender at a time before receiving an acknowledgment from the receiver. The term sliding window refers to the imaginary boxes to hold frames.

Selective Repeat ARQ is also known as the Selective Repeat Automatic Repeat Request. In this protocol, the size of the sender window is always equal to the size of the receiver window. The size of the sliding window is always greater than 1. If the receiver receives a corrupt frame, it does not directly discard it. It sends a negative acknowledgment to the sender. The sender sends that frame again as soon as on the receiving negative acknowledgment.

PSEUDOCODE:

Selective Repeat Sender Algorithm

```
begin
    frame s; //s denotes frame to be sent
    frame t; //t is temporary frame
    S_window = power(2,m-1); //Assign maximum window size
    SeqFirst = 0; // Sequence number of first frame in window
    SeqN = 0; // Sequence number of Nth frame window
    while (true) //check repeatedly
        do
            Wait_For_Event(); //wait for availability of packet
            if ( Event(Request_For_Transfer)) then
                //check if window is full
                if (SeqN-SeqFirst >= S_window) then
                    doNothing();
                end if;
                Get_Data_From_Network_Layer();
                s = Make_Frame();
                s.seq = SeqN;
                Store_Copy_Frame(s);
                Send_Frame(s);
                Start_Timer(s);
                SeqN = SeqN + 1;
            end if;
```

```

}
```

DISTANCE VECTOR ROUTING

AIM:

To write a program to implement the Distance Vector Routing.

THEORY:

Distance Vector Routing protocol is a dynamic routing protocol. With this protocol, every router in the network creates a routing table which helps them in determining the shortest path through the network. All the routers in the network are aware of every other router in the network and they keep on updating their routing table periodically. This protocol uses the principle of Bellman-Ford's algorithm.

Distance-vector routing protocols measure the distance by the number of routers a packet has to pass; one router counts as one hop. To determine the best route across a network, routers using a distance-vector protocol exchange information with one another, usually routing tables plus hop counts for destination networks and possibly other traffic information.

PSEUDOCODE:

```
begin
  for all destinations y in N:
     $D_x(y) = c(x,y)$     // If y is not a neighbour then  $c(x,y) = \infty$ 
  for each neighbour w
     $D_w(y) = ?$     for all destination y in N.
  for each neighbour w
    send distance vector  $D_x = [ D_x(y) : y \text{ in } N ]$  to w
  loop
    wait (until I receive any distance vector from some neighbour w)
    for each y in N:
       $D_x(y) = \min_v \{ c(x,v) + D_v(y) \}$ 
    If  $D_x(y)$  is changed for any destination y
      Send distance vector  $D_x = [ D_x(y) : y \text{ in } N ]$  to all neighbours
  forever
end
```

```
    printf("\n\n");  
}
```

OUTPUT:

```
$ gcc main.c
```

```
$ ./a.out
```

```
Distance Vector Routing
```

```
Enter the number of nodes : 3
```

```
Enter the cost matrix :
```

```
0  2  7
```

```
2  0  1
```

```
7  1  0
```

```
For router 1:
```

```
node 1 via 1 distance 0
```

```
node 2 via 2 distance 2
```

```
node 3 via 2 distance 3
```

```
For router 2:
```

```
node 1 via 1 distance 2
```

```
node 2 via 2 distance 0
```

```
node 3 via 3 distance 1
```

```
For router 3:
```

```
node 1 via 2 distance 3
```

```
node 2 via 2 distance 1
```

```
node 3 via 3 distance 0
```

RESULT:

The program for Distance Vector Routing was executed and output was verified successfully.

PROGRAM:

```

SIMPLE MAIL TRANSFER PROTOCOL

AIM:

To implement Simple Mail Transfer Protocol.

THEORY:

SMTP is part of the application layer of the TCP/IP protocol and traditionally operates on port 25. It utilizes a process called “store and forward” which is used to orchestrate sending your email across different networks. Within the SMTP protocol, there are smaller software services called Mail Transfer Agents that help manage the transfer of the email and its final delivery to a recipient’s mailbox. Not only does SMTP define this entire communication flow, it can also support delayed delivery of an email either at the sender site, receiver site, or at any intermediate server.

ALGORITHM:

1. *Initialize a UDF based socket connection from client to server*
2. *Client sends greeting messages to server*
3. *A greeting message with code 220 is sent from server to client*
4. *HELLO is sent from client to server to introduce itself*
5. *Server responds with code 250 and its name*
6. *MAIL FROM is sent from client to server describing name of the sender of the email.*
7. *OK from server with code 250 is sent to convey that the sender email address has been accepted.*
8. *RCPT TO is sent from client to server describing recipient name.*
9. *OK from server with 250 is sent to convey acceptance of recipient email address.*
10. *Data is sent from Client to Server to denote start of the email body.*
11. *Go ahead with body of email message is send from server with code 354.*
12. *Body of email is sent from client to server.*
13. *OK received from the server.*
14. *QUIT received from Client to Server.*
15. *Response to QUIT sent from server with code 221.*

```

printf ("\n%s", str);

printf ("\nSending response...");
strcpy( str, "250 ok");
if (sendto (sockfd, str, sizeof (str), 0, (struct sockaddr *) &client, sizeof
(client)) < 0)
    printf ("Error in sendto(!");
    sleep (3);
    if ((recvfrom (sockfd, str, sizeof (str), 0, (struct sockaddr *) &client,
&client_len)) < 0)
        printf ("Error in recvfrom(!");
        if (strncmp(str, "MAIL FROM", 9))
            printf ("'MAIL FROM' expected from client...");
        printf ("\n%s",str);

    printf ("\nSending response...");
    strcpy (str, "250 ok");
    if (sendto (sockfd, str, sizeof (str), 0, (struct sockaddr *) &client,
sizeof(client)) < 0)
        printf ("Error in sendto(!");
        sleep (3);

    }
}
```

FILE TRANSFER PROTOCOL

AIM:

To implement File Transfer Protocol.

THEORY:

FTP, which stands for File Transfer Protocol, was developed in the 1970s to allow files to be transferred between a client and a server on a computer network. The FTP protocol uses two separate channels — the command (or control) channel and the data channel — to exchange files. The command channel is responsible for accepting client connections and executing other simple commands. It typically uses server port 21. FTP clients will connect to this port to initiate a conversation for file transfer and authenticate themselves by sending a username and password.

After authentication, the client and server will then negotiate a new common server port for the data channel, over which the file will be transferred. Once the file transfer is complete, the data channel is closed. If multiple files are to be sent concurrently, a range of data channel ports must be used. The control channel remains idle until the file transfer is complete. It then reports that the file transfer was either successful or failed.

ALGORITHM:

Server

1. Create socket using `socket()` system call with address family `AF_INET`, type `SOCK_STREAM` and default protocol.
2. Bind server address and port using `bind()` system call.
3. Wait for client connection to complete accepting connections using `accept()` system call.
4. Receive the client file using `recv()` system call.
5. Using `fgets (char *str, int n, FILE *stream)` function, we need a line of text from the specified stream and store it into the string pointed by `str`. It stops when either `(n-1)` characters are read or when the end of file is reached.
6. On successful execution is when the file pointer reaches the end of file, file transfer "completed" message is sent by server to accepted client connection.

```

else
{
    while (fgets (fileread, sizeof (fileread), fp))
    {
        if(send (newsd, fileread, sizeof (fileread),0) < 0)
        {
            printf ("Cannot send file contents!\n");
        }
        sleep (1);
    }
    if (!fgets (fileread, sizeof (fileread), fp))
    {
        //when file pointer reaches end of file, file transfer "completed"
        message is send to accepted client connection using newsd, socket file descriptor.
        send (newsd, "completed", 999999999, 0);
    }
    return (0);
}
}

// Client (FTP)
#include <stdio.h>
#include <stdlib.h>
#include <sys/socket.h>
#include <netinet/in.h>
#include <unistd.h>

int main ()
{
    FILE *fp;
    int csd, n, ser, s, cli, cport, newsd;
    char name[100], rcvmsg[100], rcvg[100], fname[100];
    struct sockaddr_in servaddr;

    printf ("Enter the port: ");
    scanf ("%d", &cport);

    csd = socket (AF_INET, SOCK_STREAM, 0);
    if (csd < 0)
    {
        printf ("Error!!\n");
        exit (0);
    }
    else
        printf ("Socket is created.\n");

    servaddr.sin_family = AF_INET;
    servaddr.sin_addr.s_addr = htonl (INADDR_ANY);
    servaddr.sin_port = htons (cport);

    if (connect (csd, (struct sockaddr *) &servaddr, sizeof (servaddr)) < 0)
        printf ("Error in connection!\n");
    else
        printf ("connected.\n");
}

```

Client

1. Create socket using `socket()` system call with address family `AF_INET`, type `SOCK_STREAM` and default protocol.
2. Enter the client port number.
3. Fill in the internal socket address structure
4. Connect to the server address using `connect()` system call.
5. Read the existing and new file name from the user.
6. Send existing file to server using `send()` system call.
7. Receive feedback from server "completed" regarding file transfer completion.
8. Write file is transferred to the standard output stream.
9. Close the socket connection and file pointer

```

printf ("Enter the existing file name:\t");
scanf ("%s", name);
printf ("Enter the new file name:\t");
scanf ("%s", fname);
fp = fopen (fname, "w");
send (csd, name, sizeof (name), 0);

while (1)
{
    s = recv (csd, rcvg, 100, 0);
    rcvg[s] = '\0';
    if (strcmp (rcvg, "error") == 0)
        printf ("File is not available!\n");
    if (strcmp (rcvg, "completed") == 0)
    {
        printf ("File is transferred...\n");
        fclose (fp);
        close (csd);
        break;
    }
    else
        fputs (rcvg, stdout);
    fprintf (fp, "%s", rcvg);
    printf ("\n");

    return 0;
}
}

```

OUTPUT:

// Terminal 1

```
$ gcc -o server server.c
$ ./server
Enter the port address: 3000
Socket is created.
Binded.
```

—

// Terminal 2

```
$ gcc -o client client.c
$ ./client
Enter the port: 3000
Socket is created.
connected.
Enter the existing file name: existing-file.txt
Enter the new file name: new-file.txt
Hi Programmers!
```

// Terminal 1

```
$ gcc -o server server.c

```

LEAKY BUCKET

AIM:

To write a program to implement the Leaky Bucket.

THEORY:

The Leaky Bucket Algorithm used to control rate in a network. It is implemented as a single-server queue with constant service time. If the bucket (buffer) overflows then packets are discarded. It enforces a constant output rate (average rate) regardless of the burstiness of the input. It does nothing when input is idle. The host injects one packet per clock tick onto the network. This results in a uniform flow of packets, smoothing out bursts and reducing congestion. When packets are the same size (as in ATM cells), the one packet per tick is okay. For variable length packets though, it is better to allow a fixed number of bytes per tick.

ALGORITHM:

1. *Start.*
2. *Set the bucket size on the buffer size.*
3. *Set the output rate.*
4. *Transmit the packet such that there is no overflow.*
5. *Repeat the process of transmission at the output rate until all packets are transmitted (reject packets where its size is greater than the bucket size).*
6. *Stop.*

```

        else {
            printf("\n%d bytes transferred", b_current);
            b_current = 0;
        }

        printf("\nPackets in the bucket %d byte(s)\n", b_current);
        i++;
    }

    return 0;
}

```

OUTPUT:

```

$ gcc main.c
$ ./a.out
Enter the no. of packets: 3

Enter the packets in the order of their arrival time:
Enter the time and size: 2 600
Enter the time and size: 4 700
Enter the time and size: 5 600

Enter the bucket size: 1000
Enter the output rate: 500

At time 1
No packets to transmit
Packets in the bucket 0 byte(s)

At time 2
600 byte packet is inserted
500 bytes transferred
Packets in the bucket 100 byte(s)

At time 3
100 bytes transferred
Packets in the bucket 0 byte(s)

At time 4
700 byte packet is inserted
500 bytes transferred
Packets in the bucket 200 byte(s)

At time 5
600 byte packet is inserted
500 bytes transferred
Packets in the bucket 300 byte(s)

At time 6
300 bytes transferred
Packets in the bucket 0 byte(s)

```

RESULT:

The program for Leaky Bucket was executed and output was verified successfully.

OUTPUT:

WIRESHARK

AIM:

To understand Wireshark tool and explore its features like filters, flow graphs, statistics and protocol hierarchy.

THEORY:

Wireshark is a free and open-source packet analyzer. It is used for network troubleshooting, analysis, software and communications protocol development. It can parse and display the fields, along with their meanings as specified by different networking protocols. Wireshark uses pcap to capture packets, so it can only capture packets on the types of networks that pcap supports. Wireshark can color packets based on rules that match particular fields in packets, to help the user identify the types of traffic at a glance.

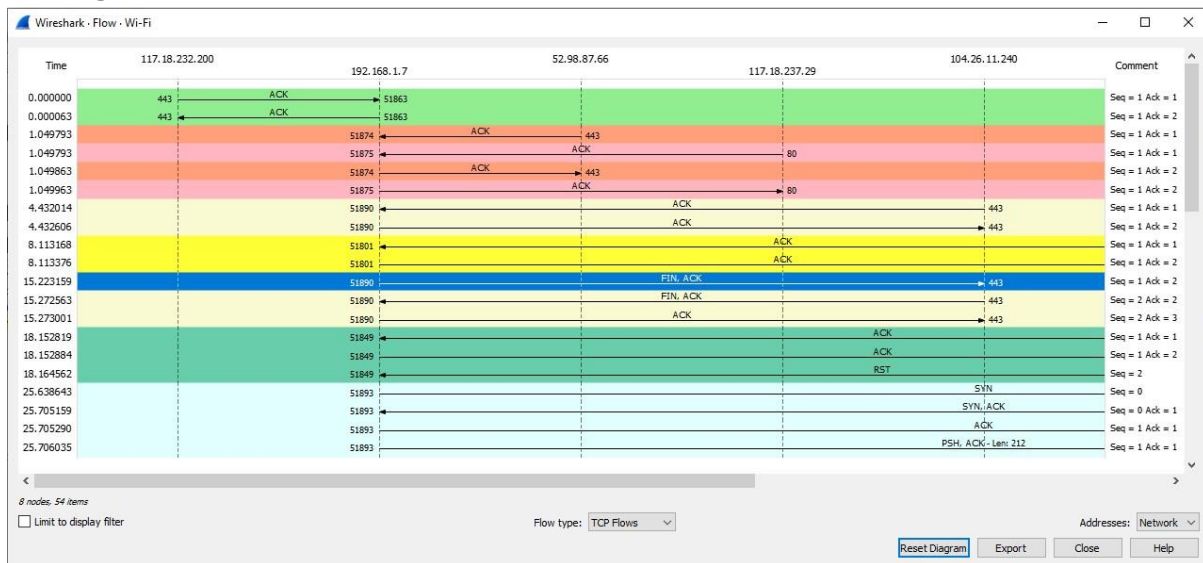

Filters: Wireshark share a powerful filter engine that helps remove the noise from a packet trace and lets you see only the packets that interest you. If a packet meets the requirements expressed in your filter, then it is displayed in the list of packets. Display filters let you compare the fields within a protocol against a specific value, compare fields against fields, and check the existence of specified fields or protocols.

Flow Graph: The Flow Graph window shows connections between hosts. It displays the packet time, direction, ports and comments for each captured connection. You can filter all connections by ICMP Flows, ICMPv6 Flows, UIM Flows and TCP Flows. Flow Graph window is used for showing multiple different topics. Each vertical line represents the specific host, which you can see in the top of the window. The numbers in each row at the very left of the window represent the time packet. The numbers at the both ends of each arrow between hosts represent the port numbers.

Statistics: Wireshark provides a wide range of network statistics. These statistics range from general information about the loaded capture file (like the number of captured packets), to statistics about specific protocols (e.g. statistics about the number of HTTP requests and responses captured). General statistics involve Summary about the capture file like: packet counts, captured time period, Protocol Hierarchy of the captured packets, Conversations like traffic between specific Ethernet/IP/... addresses etc.

Protocol Hierarchy: This is a tree of all the protocols in the capture. Each row contains the statistical values of one protocol. Two of the columns (Percent Packets and Percent Bytes) serve double duty as bar graphs. If a display filter is set it will be shown at the bottom.

Flow graphs

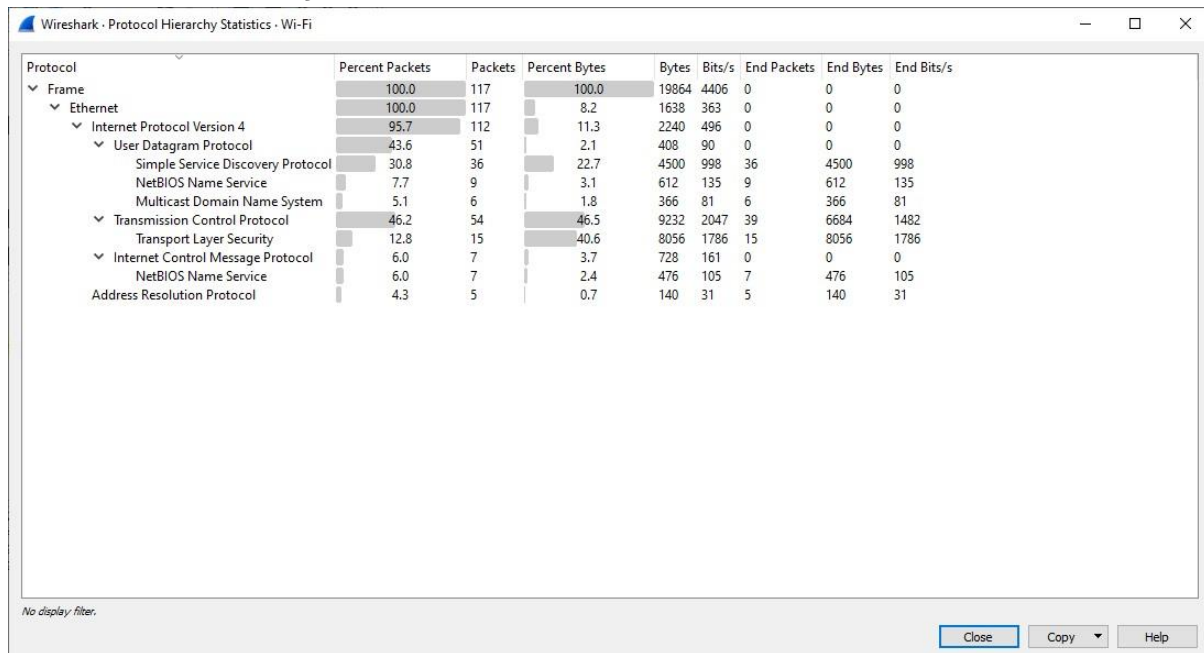

Statistics

The statistics window displays the distribution of IP addresses. The table below shows the count, average, and burst rate for each address.

Topic / Item	Count	Average	Min Val	Max Val	Rate (ms)	Percent	Burst Rate	Burst Start
▼ All Addresses	112				0.0031	100%	0.1500	25.852
52.98.87.66	4				0.0001	3.57%	0.0200	1.050
239.255.255.250	36				0.0010	32.14%	0.0600	4.432
224.0.0.251	6				0.0002	5.36%	0.0100	8.921
20.205.228.204	29				0.0008	25.89%	0.1500	25.852
20.198.119.143	2				0.0001	1.79%	0.0200	8.113
192.168.1.7	70				0.0019	62.50%	0.1500	25.852
192.168.1.5	17				0.0005	15.18%	0.0400	15.226
192.168.1.4	11				0.0003	9.82%	0.0100	6.659
192.168.1.3	14				0.0004	12.50%	0.0300	4.432
192.168.1.1	16				0.0004	14.29%	0.0200	23.941
152.199.43.62	3				0.0001	2.68%	0.0300	18.153
117.18.237.29	4				0.0001	3.57%	0.0200	1.050
117.18.232.200	7				0.0002	6.25%	0.0500	26.843
104.26.11.240	5				0.0001	4.46%	0.0300	15.223

Protocol Hierarchy

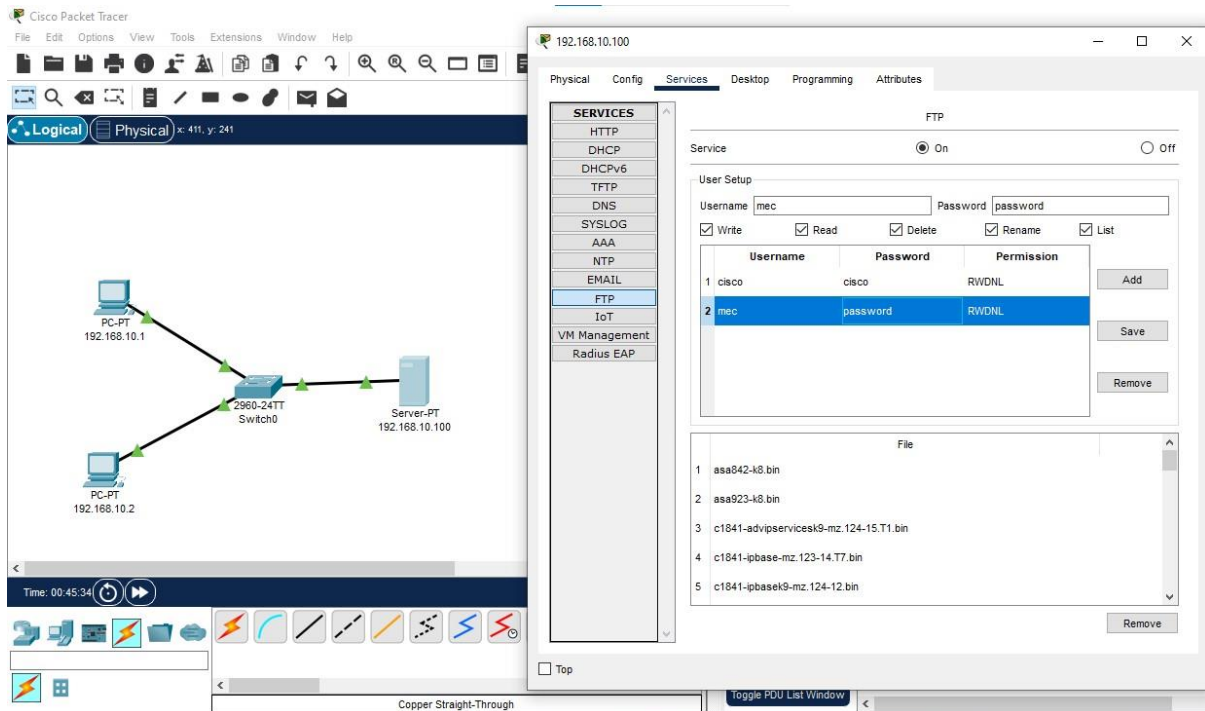

RESULT:

The experiment was executed successfully.

OUTPUT:

FTP

NETWORK WITH MULTIPLE SUBNETS

AIM:

To Study of Cisco Packet Tracer and configure FTP server, DHCP server and DNS server in a wired network using required network devices.

THEORY:

Packet Tracer is a cross-platform visual simulation tool designed by Cisco Systems that allows users to create network topologies and imitate modern computer networks. The software allows users to simulate the configuration of Cisco routers and switches using a simulated command line interface. Packet Tracer supports an array of simulated Application Layer protocols, as well as basic routing with RIP, OSPF, EIGRP and BGP.

DNS: The Domain Name System (DNS) is the hierarchical and decentralized naming system used to identify computers reachable through the Internet or other Internet Protocol (IP) networks. The resource records contained in the DNS associate domain names with other forms of information. These are most commonly used to map human-friendly domain names to the numerical IP addresses computers need to locate services and devices using the underlying network protocols.

DHCP: The Dynamic Host Configuration Protocol (DHCP) is a network management protocol used on Internet Protocol networks for automatically assigning IP addresses and other communication parameters to devices connected to the network using a client–server architecture. It employs a connectionless service model, using the User Datagram Protocol (UDP). It is implemented with two UDP port numbers, 67 is the destination port of a server, and 68 is used by the client.

DNS

The image shows the Cisco Packet Tracer interface. On the left, a network topology is visible with two PCs (192.168.10.1 and 192.168.10.2) connected to a 2960-24TT Switch, which is connected to a Server-PT (192.168.10.100). On the right, the configuration window for the Server-PT is open, specifically the 'Services' tab. The 'DNS' service is configured as follows:

- DNS Service:** On
- Resource Records:**

No.	Name	Type	Detail
0	mec.com	A Record	192.168.10.100

The image shows a web browser window with the URL <http://mec.com>. The website content is as follows:

Model Engineering College

Welcome to MEC. Opening doors to new opportunities. Mind Wide Open.

NS2 SIMULATOR

AIM:

To study of NS2 and simulate Link State Protocol and Distance Vector Routing protocol in it.

THEORY:

NS (Network Simulator) is a discrete event simulator targeted at networking research. Ns provides substantial support for simulation of TCP, routing, and multicast protocols over wired and wireless (local and satellite) networks. It is an object-oriented, discrete event-driven simulator written in C++ and Otcl/Tcl. NS-2 can be used to implement network protocols such as TCP and UDP, traffic source behavior such as FTP, Telnet, Web, CBR, and VBR, router queues management mechanism such as Drop Tail, RED, and CBQ and routing algorithms. Install NS-2 using this command :

```
sudo apt-get install ns2
```

Nam (Network Animator) is an animation tool to graphically represent the network and packet traces. Use this command:

```
sudo apt-get install nam
```

Basic Commands:

```
set a 8  
set b [expr $a/8]
```

In the first line, the variable a is assigned the value 8. In the second line, the result of the command [expr \$a/8], which equals 1, is then used as an argument to another command, which in turn assigns a value to the variable b. The “\$” sign is used to obtain a value contained in a variable and square brackets are an indication of command substitution.

Define new procedures with proc command :

```
proc factorial fact {  
    if {$fact <= 1} {  
        return 1  
    }  
    expr $fact * [factorial [expr $fact-1]]  
}
```

To open a file for reading :

```
set testfile [open hello.data r]
```

Similarly, put command is used to write data into the file.

```
set testfile [open hello.data w]  
puts $testfile "hello1"
```

```

$ns connect $udp0 $null0
$ns connect $udp1 $null1

$ns rtmodel-at 10.0 down $n11 $n5
$ns rtmodel-at 30.0 up $n11 $n5
$ns rtmodel-at 15.0 down $n7 $n6
$ns rtmodel-at 20.0 up $n7 $n6

$ns at .1 "$cbr1 start"
$ns at .2 "$cbr0 start"
$ns at 45.0 "$cbr1 stop"
$ns at 45.1 "$cbr0 stop"

$ns at 50.0 "finish"
$ns run

AWK Program for LS
BEGIN {
    print " performance evaluation"
    send=0
    recv=0
    dropped=0
    rout=0
}
{
    if($1=="+" && $3=="0" || "1" && $5=="cbr")
    {
        send++
    }
    if($1=="r" && $4=="5" && $5=="cbr")
    {
        recv++
    }
    if($1=="d")
    {
        dropped++
    }
    if($1=="r" && $5=="rtProtoLS")
    {
        rout++
    }
}

END {
    print "No of packets Send :" send
    print "No of packets Received :" recv
    print "No of packets dropped :" dropped
    print "No of routing packets :" rout
    NOH=rout/recv
    PDR=recv/send
    print "Normalised overhead :" NOH
    print "Packet delivery ratio :" PDR
}

```

To call sub processes within another process, `exec` is used, which creates a subprocess and waits for it to complete.

```
exec rm $testfile
```

To be able to run a simulation scenario, a network topology must first be created. In `ns2`, the topology consists of a collection of nodes and links.

```
set ns [new Simulator]
```

The simulator object has member functions that enable the creation of the nodes and define the links between them. The class `simulator` contains all the basic functions. Since `ns` was defined to handle the `Simulator` object, the command `$ns` is used for using the functions belonging to the `simulator` class.

In the network topology nodes can be added in the following manner:

```
set n0 [$ns node]
```

```
set n1 [$ns node]
```

Traffic agents (TCP, UDP, etc.) and traffic sources (FTP, CBR, etc.) must be set up if the node is not a router. It enables the creation of CBR traffic source using UDP as transport protocol or an FTP traffic source using TCP as a transport protocol.

CBR traffic source using UDP:

```
set udp0 [new Agent/UDP]
```

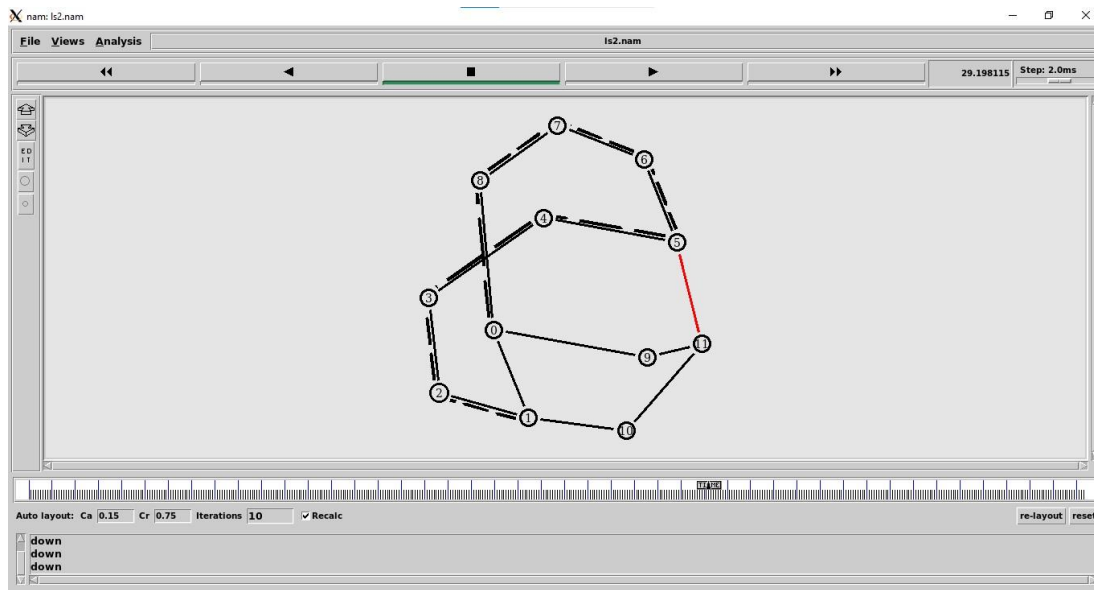

```
$ns attach-agent $n0 $udp0
```

```
set cbr0 [new Application/Traffic/CBR]
```

```
$cbr0 attach-agent $udp0
```

```
$cbr0 set packet_size_ 512
```

OUTPUT:

RESULT:

The experiment was executed successfully.
